Ver. 0.8.1

Contents

1 Introduction and Basic Usage

The Roleplaying Games Shell, `rpgsh`, is an interactive and extensible shell purpose-built for augmenting player and DM gameplay for table-top RPGs like Dungeons & Dragons®, Pathfinder®, and more!

`rpgsh` provides users with capabilities similar to those found in conventional shells like `bash` or `PowerShell` like command execution and variable assignment/modification, while also adding functionality more unique to shell environments like varying data types and variable scopes.
1.1 The Prompt

When interacting with the shell directly, you will be presented with a prompt that will look similar to the following:

```
┌[<NO_NAME>]—(0/0 (0))
└$
```

The prompt contains the currently loaded character's name (*<NO_NAME>*) along with their **current/max** *(temp)* hitpoints.

As with any command line interface, you interact with the prompt by entering in either a variable or a program, along with any operators or parameters. For example, if you want to roll a 20-sided die, you would enter the following:

```
┌[<NO_NAME>]—(0/0 (0))
└$ roll d20
```

The maximum size of the input buffer for the prompt is 256 characters. Exceeding this will throw an error.

2 Program Listing

As of version 0.8.1, the following programs are available to the user when interacting with the `rpgsh` prompt:

`banner`

Displays the ASCII art logo for `rpgsh` along with a one-line description of the program and the author's signature.

`help`

Lists all applications available to `rpgsh` along with a brief description.

`list` *

Lists all the variables in one or all scopes.

`roll` *

Dice-rolling program which supports custom lists and result counting.

`setname` *

Sets which variable is used for displaying the character's name.

`variables`

This is **NOT** to be explicitly called by the user, but is instead implicitly called when the user enters a variable as the first parameter in the prompt.

`version`

Prints `rpgsh` version.

*Program contain additional parameters. Additional information can be found by running the program with the `-?` or `--help` flag.

3 Variables

`rpgsh` allows the user to set, get, and modify variables. Variables are arranged in a nested hierarchy through three different scopes, and through an arbitrary number of levels within each scope. Operations may be performed on variables, with the following operators currently supported:

Binary: `=` , `+` , `-` , `*` , `/` , `+=` , `-=` , `*=` , `/=`
Unary: `++` , `--`

The components of an operation must be space delimited as shown below:

`$v/four = 2 + 2`   **Correct**

`$v/four=2+2`   **Incorrect**

Variables in `rpgsh` follow the below syntax:

<scope><type>[<character>]/<level 1>/<level 2>/.../<level n>

Below describes each part in detail:

3.1 scope

A single character representing which level of the overall hierarchy is being referenced. There are three total scopes for use in `rpgsh` . These are defined below:

`@` Character attributes. This scope encompasses all variables specific to a given character. If the *<character>* attribute is omitted, this references the currently loaded character.

These are stored in `~/.rpgsh/campaigns/<campaign>/characters/<charactername>.char`

`#` Campaign variables. This scope encompasses all variables in the current campaign, and are available while any character in the current campaign is loaded.

These are stored in `~/.rpgsh/campaigns/<campaign>/.vars`

`$` Shell variables. This scope encompasses all campaigns and is the broadest scope in `rpgsh` .

These are stored in `~/.rpgsh/.vars`

3.2   type

A single character representing the data type of the variable. When calling an existing variable, this parameter may be omitted, in which case `rpgsh` will find the matching variable. If more than one match is found, the first match will be used. As of version 0.8.1, the following data types have been implemented: `v` (var), `d` (dice), `c` (currency), `s` (currency system), and `w` (wallet). Note that in all operations, the data type of the returning value will always be the same as the left-hand side (LHS) of the operation. The data types are defined below:

3.2.1   var

These are generic, lazily-evaluated variables that may contain either a string or an integer, similar to how variables in many scripting languages operate. Operations performed on var-type data objects are thus dependant on whether or not the current value stored is evaluated to be a string or an integer.

For example, if you want to initialize a var character attribute called "MyVar" set to the number three, you would enter:

```
┌[<NO_NAME>]─(0/0 (0))
└$ @v/MyVar = 3
```

Alternatively, if you want to initialize that same variable to the string "three", you would enter:

```
┌[<NO_NAME>]─(0/0 (0))
└$ @v/MyVar = three
```

If you want assign a string containing spaces to a variable, it must be wrapped in quotation marks, for example:

```
┌[<NO_NAME>]─(0/0 (0))
└$ @v/MyVar = "The number three"
```

Below are the operations tables for var-type variables, the top table for var-type varibles which evaluate to an integer, and the bottom for var-type variables which evaluate to a string. Each table describes the result of an operation when the right-hand side (RHS) is of each data type. Cells marked with an **ERR** result in an error being thrown and no change being made to the LHS.

LHS evaluates to Integer

Op (Bin.)	v (Integer)	v (String)	d	c	s	w
=	Assignment	Assignment*				
+	Addition					
−	Subtraction					
*	Multiplication					
/	Division	ERR	ERR	ERR	ERR	ERR
+=	Addition Assignment					
-=	Subtraction Assignment					
*=	Multiplication Assignment					
/=	Division Assignment					

Op (Un.)	—
++	Increment
--	Decrement

LHS evaluates to String

Op (Bin.)	v (Integer)	v (String)	d	c	s	w
=	Assignment*	Assignment				
+		Concatenation				
−						
*		ERR				
/	ERR		ERR	ERR	ERR	ERR
+=		Concatenation				
-=						
*=		ERR				
/=						

Op (Un.)	—
++	ERR
--	ERR

*A warning will be thrown to indicate that the evaluated data type has changed.

7

3.2.2 dice

These are variables which contain a string of characters in the standard RPG dice format of $C\mathrm{d}F[+|-]M$, where:

- C: *(optional, assumes a value of 1 if omitted)* The count (quantity) of dice
- F: The number of faces of the di(c)e
- M: *(optional)* A modifier value

For example, if you want to initialize a dice character attribute called "MyDice" representing two six-sided dice with a modifier of +3, you would enter:

```
[<NO_NAME>]-(0/0 (0))
$ @d/MyDice = 2d6+3
```

The main purpose of having a distinct data type for what could otherwise be accomplished via a var-type variable is due to the different operations that can be performed to change the properties of the dice as is described by the below operations table:

Op (Bin.)	`v` (Integer)	`v` (String)	`d`	`c`	`s`	`w`
`=`	ERR	Assignment**	Assignment	ERR	ERR	ERR
`+`	Modfier += RHS	ERR	Count += RHS*			
`-`	Modfier -= RHS		Count -= RHS*			
`*`	Count *= RHS		ERR			
`/`	Count /= RHS					
`+=`	Modfier += RHS		Count += RHS*			
`-=`	Modfier -= RHS		Count -= RHS*			
`*=`	Count *= RHS		ERR			
`/=`	Count /= RHS					
Op (Un.)	—					
`++`	Modifier++					
`--`	Modifier--					

*If and only if both dice have equal faces. Additionally, in the event that both dice have different modifiers, a warning will be thrown indicating that only the LHS modifier will be preserved.

**If and only if the string is formatted appropriately, otherwise an error will be thrown.
